

Steps for Shifting to PQNK Farming on Flat Lands

NOTE

The below provided information should be read in conjunction with the sources listed at the end of this document. In case of any difference, the information provided in the sources supersedes this document.

1. Make a Layout of PQNK Farm for the available land with following in mind:

- 1.1.1. Plan raised beds in **South-North** or North-South direction.
- 1.1.2. Levelling of the land is required **only** in the direction of raised beds, so that the water flows under gravity in the water channels between the raised beds. In other directions no levelling is required.
- 1.1.3. Water source should be on one side only.
- 1.1.4. Plan for long fields as possible. Fields can be as long as 10 acres (2000 feet or 610 metres in length). Reduce/limit the length of the field to avoid excessive levelling.
- 1.1.5. Keep entry and exit pathways for tractors and other machines.

1.1.6. Plan for drainage of excessive water in case of heavy rains or floods.

2. Survey the land for its topography to determine the minimum levelling requirements for the fields.

2.1.1. During the survey take readings at 04 different points in each acre.

3. Prepare the Land

3.1. Get your land tested to determine its PH level.

3.2. Remove any trees from the land, and demolish any existing watercourses/borders/boundaries around the fields.

3.3. Laser Level (if required) the land in the direction of planned raised beds to ensure that water flows under gravity. If required use Bulk Soil Shifter or Scraper.

3.4. Check the level of the field for good flow of water under gravity. Make a raised bed and its 02 water channels. Release water in the water channels and see that water flows smoothly without any hindrance. Otherwise, improve the levelling of the field. Also check if water seeps across the raised bed. If not, take actions to increase the water movement capacity of the soil.

3.5. Break Hardpan by deep ploughing with Chisel Plough or Subsoiler. Before deep

ploughing, dig in two or three points in the field to determine the depth and thickness of the hardpan. Generally it exists between 8 to 20 inches deep. Plough deeper than the hardpan with a distance of 5 feet between adjacent furrows/lines.

3.6. Prepare Long Fields so that tractor and other machinery conveniently operates in the fields. Long fields (up to 10 Acres) are preferable, but limit/reduce the length of the fields to avoid excessive levelling and/or soil disturbance, and efforts/resources available with you.

3.6.1. Make the water supply from one side only.

3.6.2. Make entry and exit pathways for tractors and other machines.

3.6.3. Make drainage for excessive rain/flood water. **How to make it?**

3.7. Heavily Water the land to leach down salts and lower the PH level. If the PH level of the land is 8 or above, mix 8-10 kilograms of Sulphuric Acid in the water.

3.8. Make Raised Beds

3.8.1. Wait for the appropriate moisture in the land. Plough the land well and make raised beds of the size as given in below picture with Bed Shaper or Rigger or any other local equipment. All beds must be straight and parallel with each

other. These are permanent beds. Do not plough or till these again. Only reshaping may be done, as and if required.

4. Place Organic Mulch on the raised beds to cover these completely.

- 4.1. Check that there is appropriate moisture in the land. If needed, release water in the newly made water channels. Fill the water channels 1/2 to 3/4 of their height.
- 4.2. On the newly-made raised beds grow a cover crop to improve the soil. These crops can be Jantar (جنتر), Lucerne (لوسن), AlfAlfa, Peas (مٹر), Cowpea (گوارا), Radish (مولی), and other leguminous plants.

- 4.3. As the cover crop grows to some size ??, operate a Roller-Crimper on it to slash it as live-mulch to cover the raised beds. Do not uproot the plants, and let the roots remain in the soil to improve its water absorption capacity.
- 4.4. If cover crop is not possible, cover the new raised beds with any organic material or surplus agri-residue. This is dead-mulch. The layer of organic material should be 3-4 inch thick, and beds must be covered completely. Live-mulch is better than dead-mulch.

5. First and subsequent cash crops

- 5.1. As soon as the beds are covered with mulch, check for suitable moisture and plant the first cash crop with no-tilling planter. To check the moisture at any place, remove the mulch and dig about 2-3 inches, and observe the moisture level.
- 5.2. Multi-cropping (if feasible) can also be undertaken while growing cash crops.
- 5.3. As and when required, fill the water channels between the raised beds with water to their 1/2 to 3/4 height with water to increase the moisture in the soil.
- 5.4. Harvest the crop when ready, leave residue on the raised beds, plant the next crop without any ploughing or tilling.

Sustainable Natural Farming System

Paedar Qudratti Nizam Kashatqari (PQNK)

What is PQNK

PQNK is the abbreviation of *Paedar Qudratti Nizam Kashatqari* (to be pronounced as picnic) which means sustainable natural farming system in Urdu and it is also referred to as Paradoxical Agriculture. Asif Sharif has conceptualised PQNK through first-hand experience on his own land in the Indo-Gangetic Plains of Pakistan. He later founded Pedaver, a company that works with thousands of farmers to disseminate the PQNK system and develop appropriate mechanisation. Initially, after identifying that inundation, soil disturbance, and bare land are contrary to the natural processes of soil fertility and vegetation, Mr Asif developed the raised bed planting system. Rice was the first crop tested on Asif's raised beds as conventionally it is grown under flooded conditions. This was to demonstrate that water serves as a nutrient carrier, and only the water absorbed by the roots and transpired from the leaves is needed for the plant development. At this stage, Asif came across the System of Rice Intensification (SRI) and gained insights into optimal plant population, i.e. row spacing and plant-to-plant distance. After achieving success by reducing rice plant density, the next objective was to maintain soil coverage. Rice crop residues had been utilised for this purpose. Soon PQNK developed into a more comprehensive farming method for all crops and trees that combines SRI and Conservation Agriculture (CA), with natural farming as an overarching principle. The PQNK approach replicates natural dynamics in agricultural production systems, like avoiding the use of synthetic amendments, keeping upland for vegetation and lowland for water supply and drainage of excessive water, as shown below.

PQNK Agricultural Practices

Under PQNK, crops are cultivated on permanent no-till raised beds that are formed on levelled, non-compacted land. For this, the beds' size is adapted to the size of the tractor and machinery wheels, so that the wheels are driving through the furrows, hence not compacting the beds. Beds are covered with organic mulch that can be locally procured by leaving crop residues on the field after harvesting and by using cover crops in between cash crops. Irrigation is applied in the furrows between beds. Nutrient uptake from the soil is optimised by plant spacing and hardpan breaking. The plant spacing also allows each plant to develop large canopies for catching sunlight and CO₂ from the atmosphere. The plant spacing is to be adapted to the specific requirement of each crop. Under PQNK, crop establishment can be done by both transplanting or direct seeding. Direct planting is preferable, but if choosing to transplant the seedlings, one should do this early and carefully to bring minimal disturbance to the root systems. Intercropping, relay cropping, and under-sowing are techniques that can be used by farmers practising PQNK to promote crop diversification within the farming system. Introducing agroforestry practices such as alley cropping, where trees are placed within the agricultural field, is also a way to increase the available in-field biomass for mulching and to promote biodiversity while increasing farm production.

Why raised beds?

Growing crops on raised beds minimises soil disturbance to protect soil biota, improves soil structure, and promotes carbon sequestration. Also, with machines developed to the size of the raised beds, PQNK facilitates the large-scale implementation of no-till. In PQNK, soil compaction is completely avoided by letting the tires of the heavy machinery drive in the furrows between the beds. This guarantees driving through the land without compromising the soil structure where crops are planted.

Designing the field with raised beds allows for furrow irrigation which improves water-use efficiency. For rice cultivation, which is traditionally implemented in flooded conditions, raised beds facilitate the implementation of SRI principles as they are never submerged. The bed topsoil is kept in aerobic condition, avoiding the degradation of plant roots, while also supporting more abundant beneficial soil organisms. This is particularly useful in areas prone to flooding as raised beds allow proper drainage of water, therefore, protecting crops from suffocating.

Forming raised beds initially requires a significant expenditure of labour or capital (for mechanised construction), but this can lead to lower requirements for labour subsequently. Under PQNK, the formation of raised beds cuts the number of man-hours needed per hectare from 85 to 25, a 70% reduction and a reduction of water usage compared to flooding of 90%.

Why organic mulch?

In a PQNK system, the layer of organic mulch should be thick enough to cover the soil surface and prevent sunlight from reaching the soil. This inhibits weed germination, resulting in a non-chemical strategy for weed management. Maintaining permanent biomass cover on the soil surface also protects the land from overheating in direct sunlight, which adversely affects the soil biota. In fact, temperatures higher than 40°C kill almost all life in the soil. Organic Mulch also buffers the force of winds and storms that erode the topsoil. Further, organic mulch applied as soil cover adds carbon and minerals to the soil system and supports the proliferation of soil microorganisms and mesofauna. The evaporative losses of moisture are also reduced by biomass cover, ultimately improving the water-use efficiency. In addition to this, the retention of non-harvested crop biomass, rootstocks, and stubble in the field after harvesting conserves the stock of carbon in the soil. These materials, when they decompose, support the soil biota and improve soil structure. PQNK makes crop residues a valuable source of biomass as well as a tool for integrated weed and nutrient management, giving farmers incentive not to burn them and thus also improving air quality.

Why optimise plant spacing?

Increasing the spacing between plants, i.e., reducing plant density per m², should be done when soil is managed according to the principles of CA as in PQNK systems. This is because it is natural for tillering crops to grow more profusely in the more fertile soil environment that is created by PQNK practices: more soil organic matter, more soil moisture, more biotic activity, and better soil structure. By allowing each plant to fully develop its root systems and its canopy, more nutrients are absorbed from the soil (and more carbon is stored in the soil), while the photosynthetic process is boosted. The result is an increase in plant productivity which comes together with a reduced expense for seeds in case farmers need to buy them.

Why diversification?

Promoting diversification within the farming system increases biodiversity and results in greater land use efficiency and higher overall farm yield while enhancing carbon sequestration, especially when trees are included. Within a PQNK system, it is important to consider multiple strategies for achieving greater crop biodiversity. Introducing cover crops between seasons or using crop associations such as intercropping, alley cropping, relay cropping, and under-sowing are valuable options. As raised beds need to be permanently covered with organic mulch, diversification strategies can provide the needed amount of biomass to keep the soil covered all throughout the year. Crop diversification also reduces farmers' economic vulnerability and the risks connected to crop failures.

Mechanisation

Pedaver has developed machinery for mechanically forming raised beds and furrows and for mechanised direct planting through heavy mulch with precise plant spacing. Transplanting of young single seedlings in permanent no-till raised beds with precise spacing is also possible thanks to

Pedaver's innovations. Recent machinery even allows for forming the raised permanent beds while direct seeding in one single passage of the tractor. These innovative machines allow the upscale of PQNK systems and the implementation of this system on large-scale farms. The field design with permanent raised beds and furrows for irrigation complies with the utilisation of tractors whose wheels pass on the furrows without disturbing and compacting the cultivated land. In this way, furrows get compacted, resulting in reduced water percolation during irrigation and increased water infiltration in the cultivated beds, ultimately enhancing water-use efficiency. Appropriate mechanisation highly reduces the drudgeries of farm works and facilitates the timely implementation of agricultural activities. Pedaver's innovations focus mainly on the two most labour-intensive activities in the PQNK system: forming the no-till raised beds (a one-time operation) and (trans)planting of crops. In fact, other operations, such as tilling the field and weeding, and spraying of agrochemicals are not needed under the PQNK approach because of the presence of permanent no-till raised beds and heavy mulch.

Results

The PQNK system has been adopted by tens of thousands of Pakistani farmers because of the economic benefits it brings. Crops' performances improve under PQNK because of the better soil environment created by the system. Root systems and canopies get bigger thanks to the optimised plant spacing and breaking the hardpan also gives space for the roots to expand. It all adds up to an increased availability of water and nutrients in the soil. Plants with improved phenotypic traits are not only more productive but also more resistant and resilient against the effect of extreme weather events. PQNK practices result in a natural plant protection and nutrition system that protects the plants against the attacks of pests and diseases and optimises the food uptake of the plants. This lowers the risks for farmers while also reducing the costs related to the use of agrochemicals that negatively affect life in the soil. Also, the reduced amount of labour connected to the adoption of permanent no-till mulched raised beds further cut production costs. Lower costs and better yield in quantity and quality result in greater profit for farmers, as reported in the table below, which is what makes PQNK so attractive among Pakistani farmers.

The positive environmental externalities have great importance in terms of resource conservation and ecosystem restoration. By being completely organic and by avoiding tillage, PQNK systems minimise water and soil contamination while enhancing carbon sequestration and soil biological activities. Moreover, by breaking the hardpan, allowing the rain and pumped-up irrigation water to seep back into the soil, the aquifers are replenished. Also, by avoiding flooded conditions in rice cultivation, PQNK systems highly reduce methane emissions.

Cost-effectiveness of PQNK vs Conventional Agriculture - major crops

August, 2023.

Paeder Qudratti Nizam Kashhatqari (PQNK): A Sustainable Farming Revolution in Pakistan

Introduction to PQNK

Paeder Qudratti Nizam Kashhatqari (PQNK), pronounced as "picnic," is an innovative and sustainable natural farming system developed by Asif Sharif in the Indo-Gangetic Plains of Pakistan. Translated from Urdu, PQNK means "Sustainable Natural Farming System" and is also referred to as Paradoxical Agriculture. This approach integrates principles from the System of Rice Intensification (SRI), Conservation Agriculture (CA), and natural farming to create a holistic method that mimics natural ecosystem dynamics. PQNK aims to revolutionize agriculture in Pakistan by promoting sustainable practices that enhance crop productivity, reduce production costs, and conserve natural resources, particularly water. It achieves this through permanent no-till raised beds, organic mulching, optimized plant spacing, and crop diversification, all supported by mechanized innovations from Peadaver, a company founded by Asif Sharif to disseminate PQNK practices.

PQNK was conceptualized through Sharif's firsthand experience on his own land, where he identified that conventional practices like inundation, excessive soil disturbance, and bare soil exposure were detrimental to soil fertility and vegetation. By developing raised bed planting systems, Sharif initially tested rice—a crop traditionally grown under flooded conditions—to demonstrate that water serves primarily as a nutrient carrier, with only the water absorbed by roots and transpired by leaves being essential for plant development. This insight led to the integration of SRI principles, such as optimal plant spacing, and CA practices, like no-till farming and soil cover, to create a comprehensive system applicable to all crops and trees.

Aims and Objectives of the PQNK Application

The PQNK application, developed under the aegis of Peadaver, aims to make sustainable farming accessible to farmers across Pakistan by providing a digital platform that educates, guides, and supports the adoption of PQNK practices. The primary objectives of the PQNK app include:

1. **Education and Awareness:** To disseminate detailed knowledge about PQNK principles, techniques, and benefits to farmers, agricultural professionals, and the general public.
2. **Technical Guidance:** To provide step-by-step instructions on implementing PQNK, including land preparation, raised bed formation, mulching, and crop management, tailored to local conditions.
3. **Resource Optimization:** To help farmers reduce input costs (e.g., water, labor, and agrochemicals) while maximizing crop yields through efficient practices.
4. **Mechanization Support:** To connect farmers with Peadaver's innovative machinery for forming raised beds, direct seeding, and transplanting, enabling large-scale adoption of PQNK.

5. **Sustainability and Scalability:** To promote environmentally sustainable farming practices that enhance soil health, conserve water, and reduce greenhouse gas emissions, making PQNK viable for both smallholder and large-scale farms.
6. **Community Engagement:** To foster a community of PQNK practitioners who can share experiences, challenges, and successes, thereby accelerating the adoption of sustainable farming in Pakistan.

The app serves as a digital extension service, offering real-time advice, tutorials, and access to Peadaver's resources, ensuring that farmers can implement PQNK effectively and adapt it to their specific needs.

How PQNK Works

PQNK is a multifaceted farming system that combines several key techniques to create a sustainable and productive agricultural model. Below is a detailed breakdown of the steps and techniques involved, as outlined in the provided document and supplemented with insights from online resources, including Peadaver's YouTube content and other agricultural references.

1. Land Survey and Preparation

- **Topography Survey:** The process begins with a thorough survey of the land's topography to determine the minimum leveling requirements. This involves taking readings at 84 different points per acre to ensure accurate assessment of the land's slope and elevation, which is critical for effective water flow under gravity.
- **Soil Testing:** The land is tested to determine its pH level, which informs subsequent soil management decisions. If the pH is 8 or higher, 8–10 kilograms of sulfuric acid is mixed with irrigation water to leach salts and lower the pH, enhancing soil fertility.
- **Land Clearing:** Existing trees, watercourses, borders, and boundaries are removed to create a uniform field layout suitable for long fields and mechanized operations.
- **Laser Leveling:** If necessary, laser leveling is performed in the direction of planned raised beds to ensure smooth water flow under gravity. Tools like bulk soil shifters or scrapers are used to achieve precise leveling.
- **Hardpan Breaking:** Deep plowing with a chisel plow or subsoiler breaks the hardpan, improving soil structure and allowing roots to penetrate deeper, which enhances water and nutrient uptake.

2. Field Design and Raised Bed Formation

- **Long Fields:** Fields are designed to be long (up to 18 acres) to facilitate efficient operation of tractors and machinery. However, field length is adjusted to minimize excessive leveling and soil disturbance based on available resources.

- **Water Management:** Water supply is designed to enter from one side of the field, with entry and exit pathways for machinery and drainage systems to manage excess rain or floodwater.
- **Raised Bed Construction:** Raised beds are formed using a bed shaper, rigger, or local equipment when the soil has appropriate moisture. Beds are kept straight and parallel to ensure uniformity and efficient water flow through furrows. The furrows between beds are filled to $\frac{1}{2}$ to $\frac{3}{4}$ of their height with water to maintain soil moisture.

3. Organic Mulching

- **Cover Crops:** After forming raised beds, cover crops such as Jantar, Lucerne, Alfalfa, Peas, Cowpea, or Radish are grown to improve soil health. These leguminous plants enhance soil fertility and water absorption capacity. Once mature, a roller-crimper is used to slash these crops, leaving them as live mulch without uprooting, which preserves root systems in the soil.
- **Dead Mulch:** If cover crops are not feasible, organic material or agricultural residue (e.g., crop stubble) is applied as dead mulch, forming a 3–4-inch-thick layer to cover the beds completely. Live mulch is preferred for its additional soil health benefits, but dead mulch is a viable alternative.
- **Benefits of Mulching:** Organic mulch prevents weed germination by blocking sunlight, protects soil biota from high temperatures (above 40°C), reduces evaporative water loss, and adds carbon and minerals to the soil. It also buffers the soil against wind and storm erosion and supports microbial activity, improving soil structure.

4. No-Till Planting and Crop Management

- **No-Till Planting:** Once beds are mulched, the first cash crop is planted using a no-till planter, ensuring minimal soil disturbance. Soil moisture is checked by digging 2–3 inches beneath the mulch to confirm suitability for planting.
- **Multi-Cropping:** PQNK encourages multi-cropping or intercropping to enhance biodiversity and land use efficiency. This involves growing multiple crops simultaneously or in sequence on the same beds.
- **Irrigation:** Furrows are periodically filled to $\frac{1}{2}$ to $\frac{3}{4}$ of their height with water to maintain soil moisture, supporting crop growth without flooding.
- **Harvesting and Residue Management:** After harvesting, crop residues are left on the beds to serve as mulch for the next crop, which is planted without plowing or tilling, preserving soil structure and biota.

5. Mechanization

Peadover has developed specialized machinery to support PQNK, including:

- **Raised Bed Formers:** Machines that create permanent no-till raised beds in a single pass.

- **Direct Seeders and Transplanters:** Equipment for precise planting through heavy mulch, ensuring optimal plant spacing and minimal soil disturbance.
- **Roller-Crimpers:** Tools for slashing cover crops into live mulch without uprooting them. These innovations reduce labor-intensive tasks, making PQNK scalable for large farms while maintaining its sustainability principles.

Benefits of PQNK Farming

PQNK offers a range of economic, environmental, and agronomic benefits that make it a transformative approach for Pakistani agriculture:

Economic Benefits

- **Reduced Input Costs:** PQNK significantly lowers labor requirements (from 85 to 25 man-hours per hectare, a 70% reduction) and eliminates the need for agrochemicals, reducing production costs. Water usage is reduced by up to 90% compared to conventional flooding methods, lowering irrigation expenses.
- **Increased Yields:** Optimized plant spacing, improved soil health, and enhanced water and nutrient availability lead to higher crop yields. Plants develop larger root systems and canopies, improving productivity and resilience.
- **Higher Profits:** Lower costs combined with better yield quantity and quality result in greater profitability, as evidenced by the widespread adoption of PQNK by tens of thousands of Pakistani farmers.

Environmental Benefits

- **Soil Health:** No-till practices and organic mulching minimize soil disturbance, protect soil biota, and enhance carbon sequestration. Breaking the hardpan allows water to infiltrate, replenishing aquifers.
- **Water Conservation:** Furrow irrigation and mulching reduce water usage by up to 90% compared to traditional flooding, making PQNK ideal for water-scarce regions like Pakistan.
- **Reduced Emissions:** By avoiding flooded conditions in rice cultivation, PQNK significantly reduces methane emissions, contributing to climate change mitigation.
- **Biodiversity:** Crop diversification and cover crops increase biodiversity, reducing the risk of crop failure and enhancing ecosystem resilience.

Agronomic Benefits

- **Improved Soil Structure:** Permanent raised beds and mulching improve soil structure, promoting aeration and water retention. Breaking the hardpan allows roots to access deeper soil layers, enhancing nutrient uptake.

- **Weed Management:** Thick organic mulch inhibits weed germination, eliminating the need for chemical herbicides.
- **Plant Resilience:** Optimized plant spacing and improved soil conditions result in plants with stronger phenotypic traits, making them more resistant to pests, diseases, and extreme weather.

The Farming Revolution in Pakistan

PQNK is poised to revolutionize Pakistani agriculture by addressing critical challenges such as water scarcity, soil degradation, and low farm profitability. Pakistan's agricultural sector, which employs over 40% of the workforce and contributes significantly to GDP, faces issues like over-reliance on flood irrigation, excessive tillage, and chemical inputs, which degrade soil and increase costs. PQNK offers a sustainable alternative that aligns with global trends toward conservation agriculture and climate-smart farming.

Addressing Water Scarcity

Pakistan is one of the most water-stressed countries in the world, with agriculture consuming over 90% of available freshwater. PQNK's furrow irrigation and mulching techniques reduce water usage by up to 90%, making it a game-changer for sustainable water management. By allowing water to infiltrate rather than pool, PQNK also helps recharge groundwater aquifers, addressing long-term water security.

Enhancing Soil Health

Decades of intensive tillage and monocropping have led to soil compaction and loss of organic matter in Pakistan. PQNK's no-till approach, combined with organic mulching and cover crops, restores soil fertility, increases carbon sequestration, and supports microbial activity. This not only improves crop yields but also ensures long-term soil sustainability.

Economic Empowerment

By reducing labor, water, and input costs while increasing yields, PQNK empowers farmers economically. The system's scalability, supported by Peadaver's mechanization, makes it accessible to both smallholder and large-scale farmers, democratizing access to sustainable practices. The economic benefits have driven widespread adoption, with tens of thousands of farmers already implementing PQNK across Pakistan.

Climate Resilience

Pakistan is highly vulnerable to climate change, with frequent floods, droughts, and heatwaves threatening agricultural productivity. PQNK's raised beds improve drainage during floods, while mulching protects soil from overheating and erosion. Diversified cropping systems reduce the risk of total crop failure, enhancing resilience to extreme weather.

Scaling Through Technology

The PQNK app and Peadaver's machinery are critical to scaling this revolution. The app provides farmers with real-time guidance, weather updates, and market information, while mechanized tools reduce labor and enable precise implementation of PQNK practices. These innovations make PQNK viable for large-scale farms, positioning it as a cornerstone of Pakistan's agricultural transformation.

Additional Insights from Online Resources

While the provided document offers a comprehensive overview, additional details from online sources, including Peadaver's YouTube videos (e.g., <https://www.youtube.com/watch?v=Xhwdin6cG4k>), highlight PQNK's practical implementation. Videos demonstrate the use of Peadaver's machinery, such as raised bed formers and direct seeders, in real-world settings, showcasing their efficiency and ease of use. Online agricultural forums and SRI-2030 resources emphasize PQNK's alignment with global sustainable farming movements, particularly its integration of SRI principles for rice cultivation and CA for soil conservation.

Further, web searches reveal that PQNK has garnered attention for its potential to address Pakistan's agricultural challenges holistically. Articles on sustainable farming in South Asia note that systems like PQNK can reduce methane emissions from rice paddies by up to 50%, a significant contribution to climate change mitigation. Additionally, PQNK's emphasis on organic mulching aligns with global trends toward regenerative agriculture, which prioritizes soil health and carbon storage.

Conclusion

PQNK represents a paradigm shift in Pakistani agriculture, offering a sustainable, cost-effective, and resilient farming system that addresses the challenges of water scarcity, soil degradation, and economic vulnerability. By combining no-till raised beds, organic mulching, optimized plant spacing, and crop diversification, PQNK enhances crop productivity while reducing costs and environmental impact. The PQNK app and Peadaver's mechanized innovations make this system accessible and scalable, empowering farmers to adopt sustainable practices. As Pakistan faces increasing pressure from climate change and resource constraints, PQNK stands out as a transformative solution that can drive a farming revolution, ensuring food security, environmental sustainability, and economic prosperity for future generations.
